

The lattice and quantized Yang-Mills theory

Michael Creutz

Brookhaven Lab

Yang-Mills Gluons

Fields that hold quarks together in subnuclear particles

- much like electric fields except
 - 8 electric fields, not just one: “non-Abelian” fields
 - charged with respect to each other

The topic of this meeting

Quarks

Fundamental constituents feeling the nuclear force

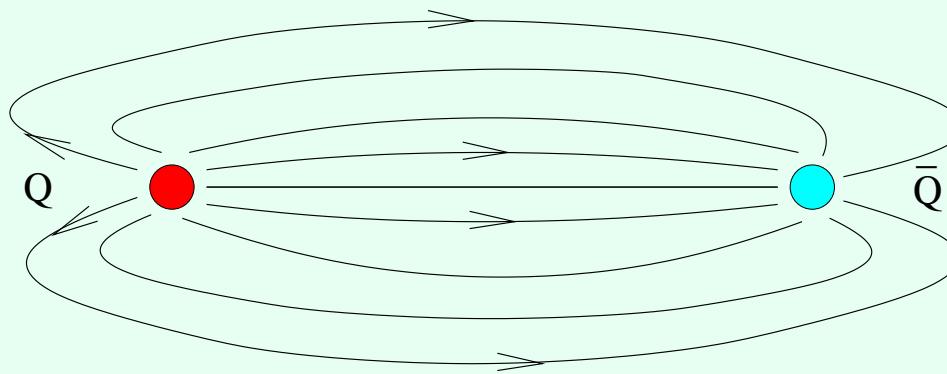

- six known types: u, d, s, c, b, t
- proton (uud); neutron (udd)

Why do we believe in them?

- various combinations give families of observed particles
- high energy scattering suggests pointlike substructure
- heavy quark bound states, i.e. $J = (c\bar{c})$
 - “hydrogen atoms” for quarks

Confinement: quarks cannot be isolated

- self interacting gluon flux lines do not spread out

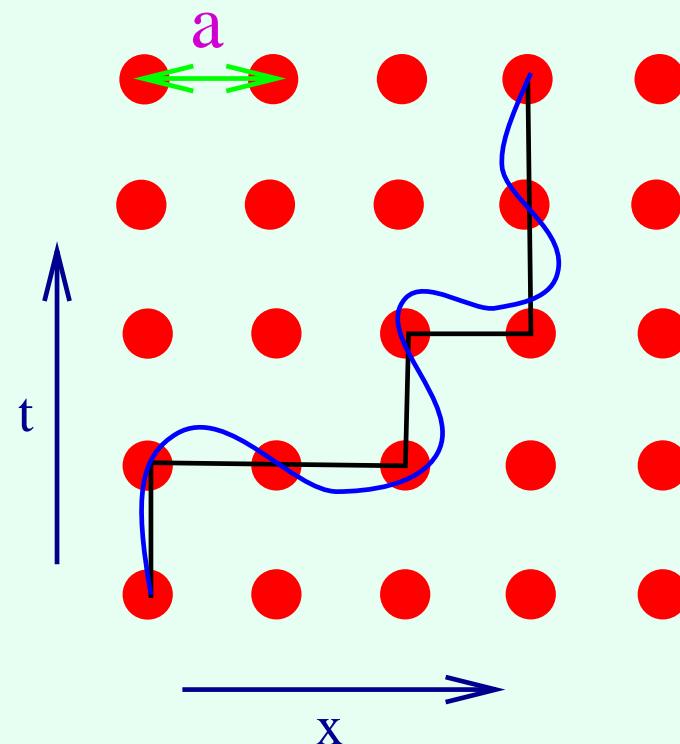

- $1/r^2$ force replaced by a constant at long distances
 - quarks at ends of “strings”

Constant 14 tons of tension pulling the quarks together

Lattices

Quark paths or “world lines” \rightarrow discrete hops

- four dimensions of space and time

The lattice is a mathematical trick

- lattice spacing $a \rightarrow 0$ for physics
 - $a = \text{minimum length (cutoff)} = \pi/\Lambda$

Why

- defines quantum field theory as a limiting process
- allows numerical computations

What led us to the lattice?

Late 1960's

- quantum electrodynamics: immensely successful, but “done”
- eightfold way: “quarks” explain particle families
- electroweak theory emerging
- electron-proton scattering: “partons”

Meson-nucleon theory failing

- $\frac{g^2}{4\pi} \sim 15$ vs. $\frac{e^2}{4\pi} \sim \frac{1}{137}$
- no small parameter for expansion

Frustration with quantum field theory

“S-matrix theory”

- particles are bound states of themselves
 - $p + \pi \leftrightarrow \Delta$
 - $\Delta + \pi \leftrightarrow p$
- held together by exchanging themselves
- roots of duality between particles and forces \longrightarrow string theory

What is elementary?

Early 1970's

- “partons” \longleftrightarrow “quarks”
- renormalizability of non-Abelian gauge theories
 - 1999 Nobel Prize, G. 't Hooft and M. Veltman
- asymptotic freedom
 - 2004 Nobel prize: D. Gross, D. Politzer, F. Wilczek
- Quark Confining Dynamics (QCD) evolving

Confinement?

- interacting hadrons vs. quarks and gluons
- What is elementary?

Mid 1970's: a particle theory revolution

- J/ψ discovered, quarks inescapable
- field theory reborn: “standard model”

Extended objects in field theory

- “classical lumps” a new way to get particles
- **Bosonization:** very different formulations can be equivalent
- growing connections with statistical mechanics
- **What is elementary?**

Field Theory >> Feynman Diagrams

Field theory has infinities

- bare charge, mass divergent
- must “regulate” for calculation
- Pauli Villars, dimensional regularization, ...: perturbative
 - based on Feynman diagrams
 - an expansion in a small parameter, the electric charge

But the expansion misses important “non-perturbative” effects

- confinement
- light pions from chiral symmetry breaking
- no small parameter to expand in

need a “non-perturbative” regulator

Wilson's strong coupling lattice theory (1973)

Strong coupling limit does confine quarks

- only quark bound states (hadrons) can move

space-time lattice = non-perturbative cutoff

Lattice gauge theory

- A mathematical trick
- Minimum wavelength = lattice spacing a
 - Uncertainty principle: a maximum momentum = π/a
- Allows computations
- Defines a field theory

Wilson's strong coupling lattice theory (1973)

Strong coupling limit does confine quarks

- only quark bound states (hadrons) can move

space-time lattice = non-perturbative cutoff

Lattice gauge theory

- A mathematical trick
- Minimum wavelength = lattice spacing a
 - Uncertainty principle: a maximum momentum = π/a
- Allows computations
- Defines a field theory

Be discrete, do it on the lattice

Wilson's strong coupling lattice theory (1973)

Strong coupling limit does confine quarks

- only quark bound states (hadrons) can move

space-time lattice = non-perturbative cutoff

Lattice gauge theory

- A mathematical trick
- Minimum wavelength = lattice spacing a
 - Uncertainty principle: a maximum momentum = π/a
- Allows computations
- Defines a field theory

Be discrete, do it on the lattice

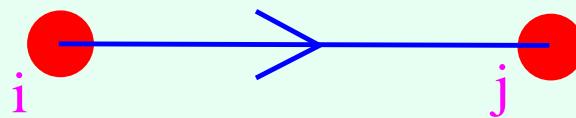

Be indiscreet, do it continuously

Wilson's formulation

local symmetry + theory of phases

Variables:

- Gauge fields are generalized “phases”
 - $U_{i,j} \sim \exp(i \int_{x_i}^{x_j} A^\mu dx_\mu)$

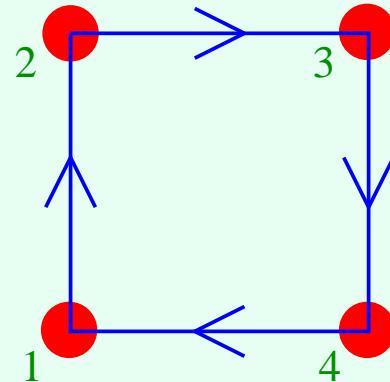

U_{ij} = 3 by 3 unitary ($U^\dagger U = 1$) matrices, i.e. SU(3)

- On links connecting nearest neighbors
- 3 quarks in a proton

Dynamics:

- Sum over elementary squares, “plaquettes”

$$U_p = U_{1,2}U_{2,3}U_{3,4}U_{4,1}$$

- like a “curl” $\vec{\nabla} \times \vec{A} = \vec{B}$
- flux through corresponding plaquette.

$$S = \int d^4x (E^2 + B^2) \rightarrow \sum_p \left(1 - \frac{1}{3} \text{ReTr} U_p \right)$$

Quantum mechanics:

- via Feynman's path integrals
- sum over paths \rightarrow sum over phases
 - $Z = \int(dU)e^{-\beta S}$
 - invariant group measure

Parameter β related to the “bare” charge

- $\beta = \frac{6}{g_0^2}$
- divergences say we must “renormalize” β as $a \rightarrow 0$
 - adjust β to hold some physical quantity constant

Parameters

Asymptotic freedom

- 2004 Nobel prize: D. Gross, D. Politzer, F. Wilczek

$$g_0^2 \sim \frac{1}{\log(1/a\Lambda)} \longrightarrow_{a \rightarrow 0} 0$$

Λ sets the overall scale via “dimensional transmutation”

- Sidney Coleman and Erick Weinberg
- Λ depends on units: not a real parameter

Only the quark masses!

Only the quark masses!

$m_q = 0$: parameter free theory

- $m_\pi = 0$
- m_ρ/m_p determined
- close to reality

Numerical Simulation

$$Z = \int dU e^{-\beta S}$$

10^4 lattice \Rightarrow

- $10^4 \times 4 \times 8 = 320,000$ dimensional integral
- 2 points/dimension \Rightarrow

$$2^{320,000} = 3.8 \times 10^{96,329} \quad \text{terms}$$

- age of universe $\sim 10^{27}$ nanoseconds

Use statistical methods

- $Z \longleftrightarrow$ partition function
- $\frac{1}{\beta} \longleftrightarrow$ temperature

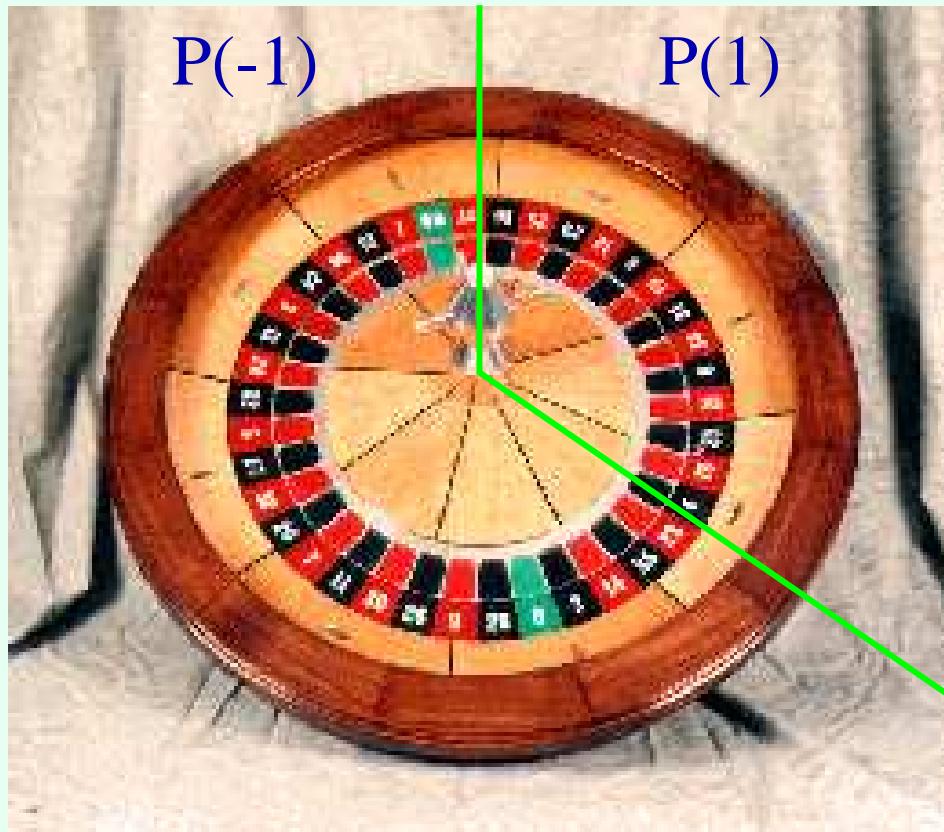

Find “typical equilibrium” configurations C

- $P(C) \sim e^{-\beta S(C)}$ Use a Markov process
- $C \rightarrow C' \rightarrow \dots$

Z_2 example: (L. Jacobs, C. Rebbi, MC)

$$U = \pm 1$$

$$P(1) = \frac{e^{-\beta S(1)}}{e^{-\beta S(1)} + e^{-\beta S(-1)}}$$

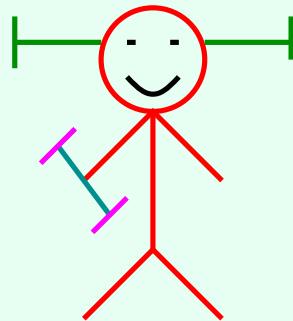

Random field changes biased by Boltzmann weight.

- converge towards “thermal equilibrium.”
 - $P(C) \sim e^{-\beta S}$

In principle can measure anything

Fluctuations → theorists have error bars!

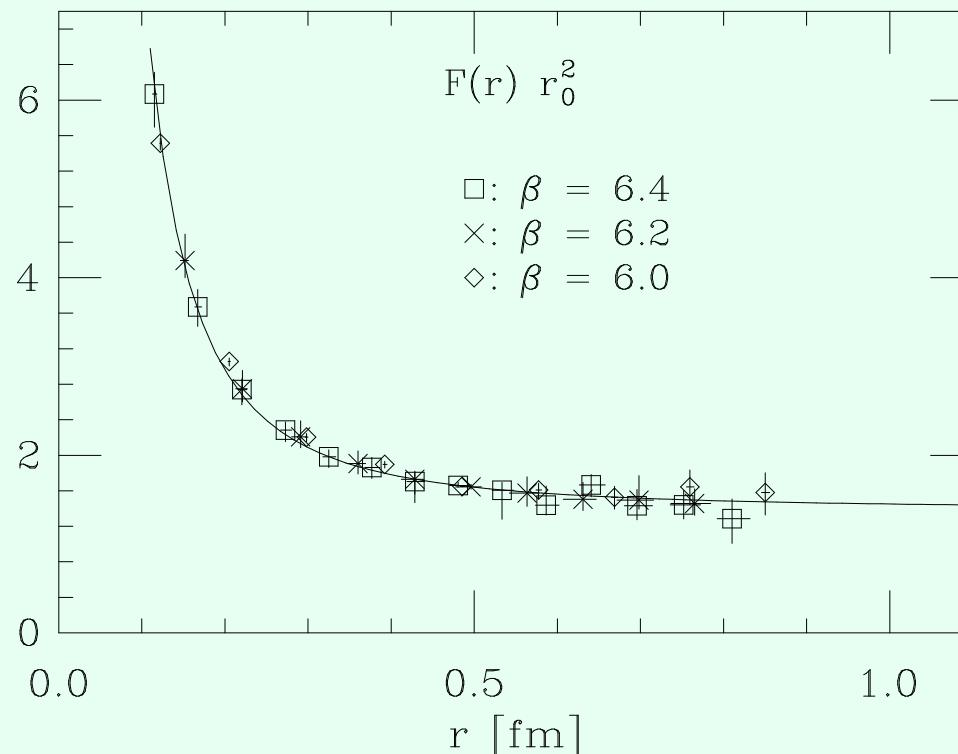

Also have systematic errors

- finite volume
- finite lattice spacing
- quark mass extrapolations

Interquark force

- constant at large distance
- confinement

UKQCD Collaboration, hep-lat/9411075

Extracting particle masses

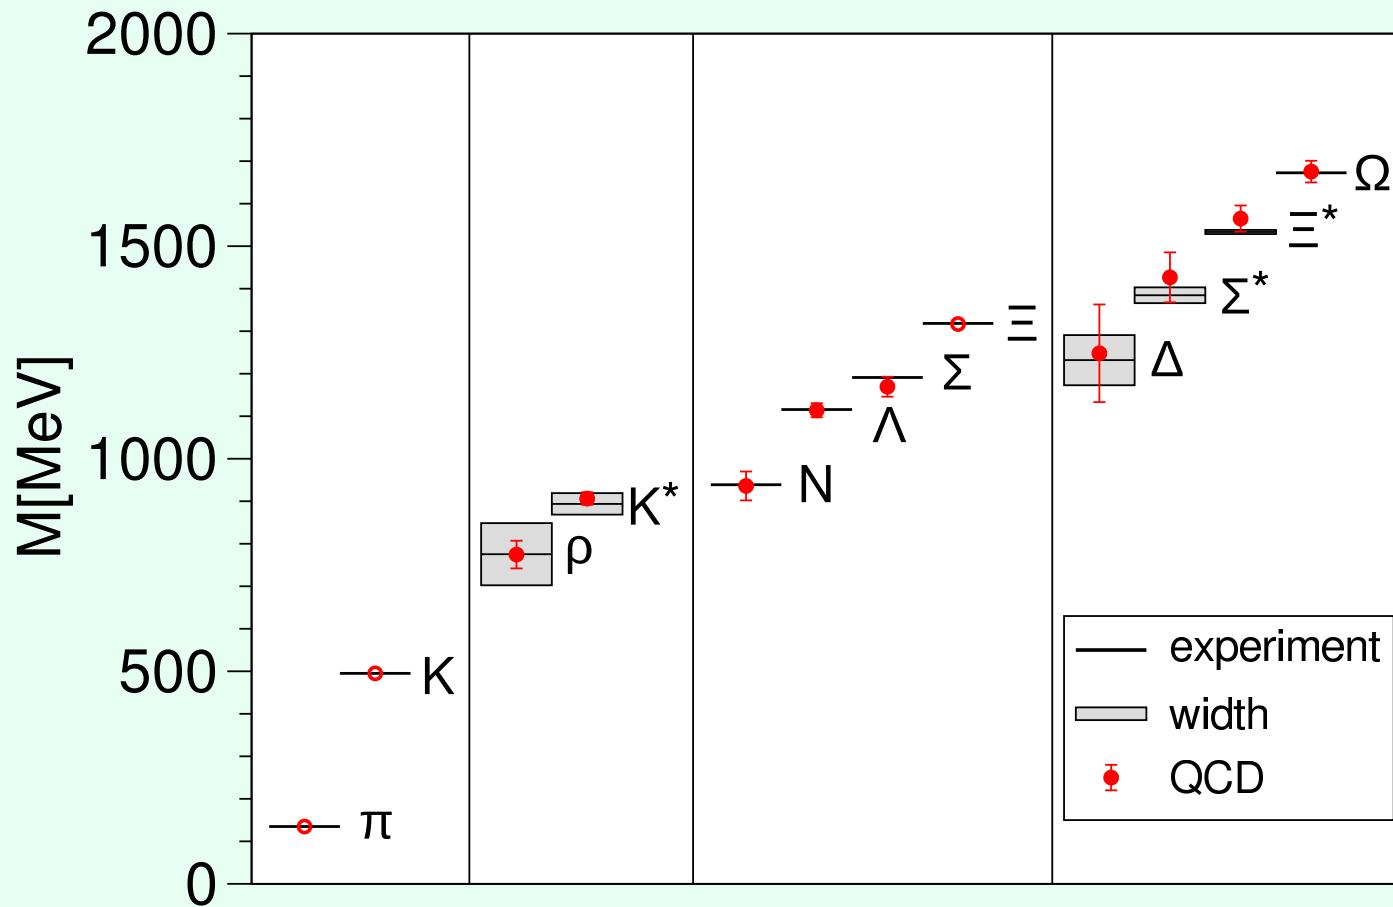

- let $\phi(t)$ be some operator that can create a particle at time t
- As $t \rightarrow \infty$
 - $\langle \phi(t)\phi(0) \rangle \longrightarrow e^{-mt}$
- m = mass of lightest hadron created by ϕ
- Bare quark mass is a parameter

Chiral symmetry:

$$m_\pi^2 \sim m_q$$

Adjust m_q to get m_π/m_ρ (m_s for the kaon)

all other mass ratios determined

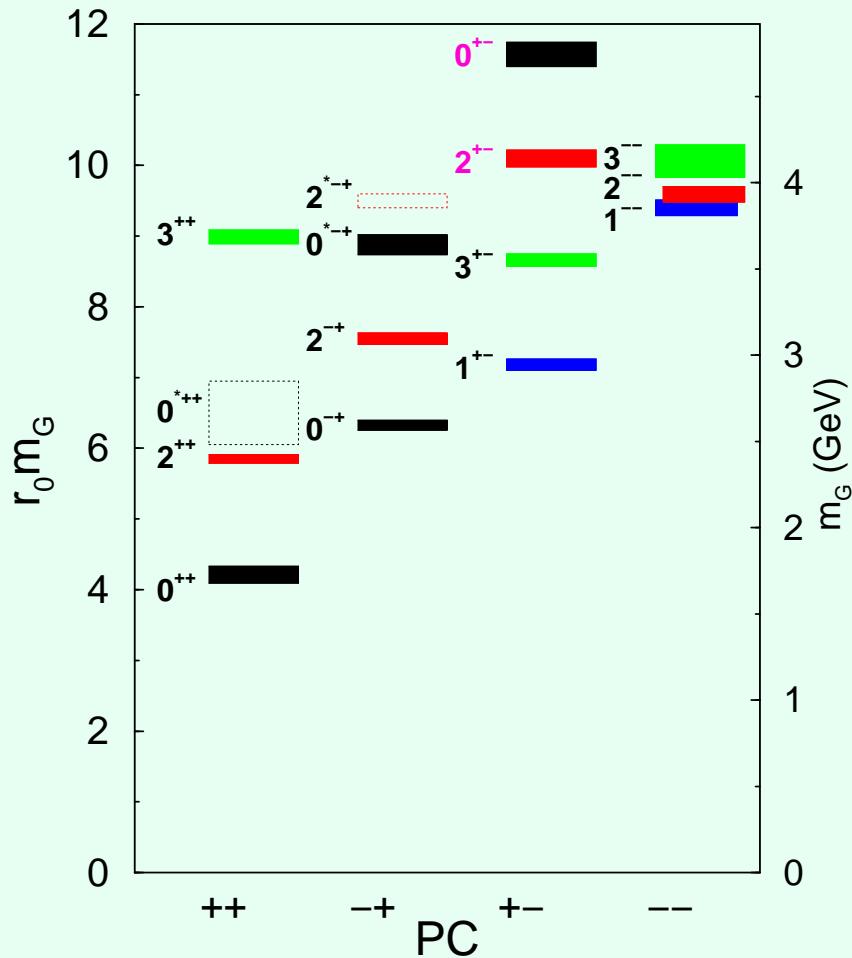

Budapest-Marseille-Wuppertal collaboration

- Lattice 2008 conference
- Science 322:1224-1227,2008
- improved Wilson fermions

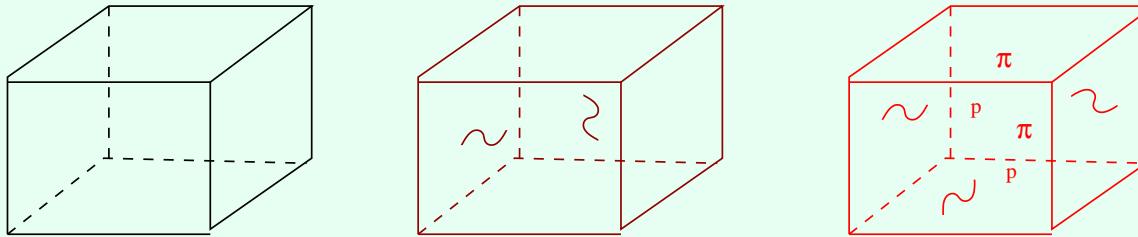

Glueballs

- closed loops of gluon flux
- no quarks

Morningstar and Peardon, Phys. Rev. D 60, 034509 (1999)
• anisotropic lattice, ignoring virtual quark-antiquark pairs

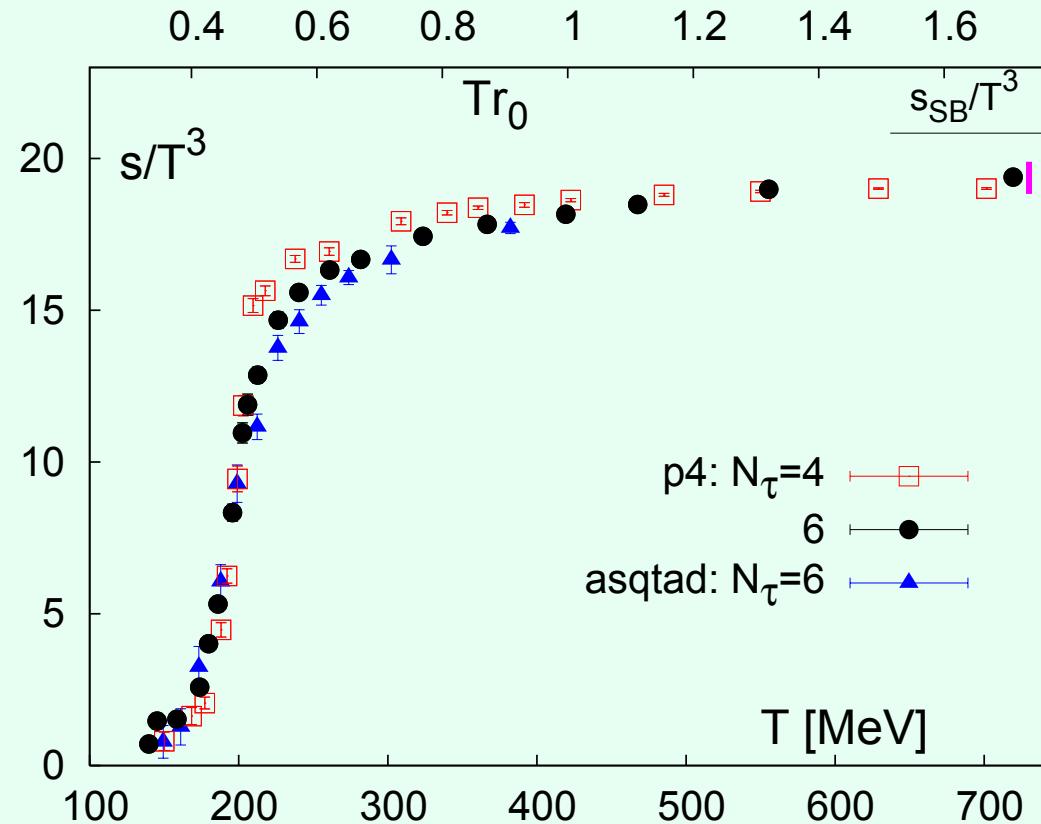

Quark Gluon Plasma

Finite temporal box of length t

- $Z \sim \text{Tr } e^{-Ht}$
- $1/t \leftrightarrow \text{temperature}$
- confinement lost at high temperature
- chiral symmetry restored
- $T_c \sim 170 - 190 \text{ MeV}$
 - not a true transition, but a rapid “crossover”

Big jump in entropy versus temperature

M. Cheng et al., Phys.Rev.D77:014511,2008.

- uses a non-rigorous approximation to QCD

Unsolved Problems

Chiral gauge theories

- parity conserving theories in good shape
- chiral theories (neutrinos) remain enigmatic
 - non-perturbative definition of the weak interactions?

Sign problems

- finite baryon density: nuclear matter
 - color superconductivity at high density?

What is elementary?

Lots of room for new ideas!
